Atomic Clock

Introducing the Atomic clock

An atomic clock is a clock device that uses a hyperfine transition frequency in the microwave, or electron transition frequency in the optical, or ultraviolet region of the electromagnetic spectrum of atoms as a frequency standard for its timekeeping element. Atomic clocks are the most accurate time and frequency standards known, and are used as primary standards for international time distribution services, to control the wave frequency of television broadcasts, and in global navigation satellite systems such as GPS.

The principle of operation of an atomic clock is based on atomic physics; it measures the electromagnetic signal that electrons in atoms emit when they change energy levels. Early atomic clocks were based on masers at room temperature. Since 2004, more accurate atomic clocks first cool the atoms to near absolute zero temperature by slowing them with lasers and probing them in atomic fountains in a microwave-filled cavity. An example of this is the NIST-F1 atomic clock, one of the national primary time and frequency standards of the United States.

The accuracy of an atomic clock depends on two factors: the first is temperature of the sample atoms—colder atoms move much more slowly, allowing longer probe times, the second is the frequency and intrinsic linewidth of the electronic or hyperfine transition. Higher frequencies and narrow lines increase the precision.

National standards agencies in many countries maintain a network of atomic clocks which are intercompared and kept synchronized to an accuracy of 10^{-9} seconds per day (approximately 1 part in 1014). These clocks collectively define a continuous and stable time scale, the International Atomic Time (TAI). For civil time, another time scale is disseminated, Coordinated Universal Time (UTC). UTC is derived from TAI, but has added leap seconds from UT1, to account for variations in the rotation of the Earth with respect to the solar time.

Quartz Clock

Introducing the Quartz Clock

A quartz clock is a clock that uses an electronic oscillator that is regulated by a quartz crystal to keep time. This crystal oscillator creates a signal with very precise frequency, so that quartz clocks are at least an order of magnitude more accurate than mechanical clocks. Generally, some form of digital logic counts the cycles of this signal and provides a numeric time display, usually in units of hours, minutes, and seconds.

The world's first quartz clock was built in 1927 by Warren Morrison and J. W. Horton at Bell Telephone Laboratories. The world's first quartz watch, however, was unveiled by Seiko as the Astron in December 1969. Since the 1980s, when the advent of solid-state digital electronics allowed them to be made compact and inexpensive, quartz timekeepers have become the world's most widely used timekeeping technology, used in most clocks and watches as well as computers and other appliances that keep time.

Quartz crystal ageing

Clock quartz crystals are manufactured in an ultra-clean environment and protected by an inert ultra-high-vacuum environment in hermetically sealed containers. Still the frequency of a quartz crystal can slowly change over time causing the frequency to increase or decrease over time. The effect of ageing is much smaller than the effect of frequency variation caused by temperature changes and manufacturers can estimate its effects.

Generally, the ageing effect eventually decreases the frequency. Factors that can cause a small frequency drift over time are stress relief in the mounting structure, loss of hermetic seal, contaminations contained in the crystal lattice, moisture absorption, changes in or on the quartz crystal, severe shock and vibrations effects, exposure to very high temperatures. Crystal aging tends to be logarithmic meaning the maximum rate of change of frequency occurs immediately after manufacture and decays thereafter.

Most of the aging will occur within the first year of the crystals service life. Crystals do eventually stop aging (asymptotically), but it can take many years. Movement manufacturers can pre-age crystals before assembling them into clock movements. To promote accelerated ageing the crystals are exposed to high temperatures.

If a crystal is pre-aged, the manufacturer can measure its ageing rates (strictly, the coefficients in the ageing formula) and have a microcontroller calculate out the corrections over time. The initial calibration of a movement will stay accurate longer if the crystals are pre-aged. The advantage would end after subsequent regulation which will, reset any cumulative ageing error to zero. A reason more expensive movements tend to be more accurate is that the crystals are pre-aged longer and selected for better ageing performance. Sometimes individual crystals after pre-ageing are hand selected for high-accuracy movement performance.

The piezoelectric properties of quartz were discovered by Jacques and Pierre Curie in 1880. The first quartz crystal oscillator was built by Walter G. Cady in 1921. In 1923, D. W. Dye at the National Physical Laboratory in the UK and Warren Morrison at Bell Telephone Laboratories produced sequences of precision time signals with quartz oscillators. In 1927, the first quartz clock was built by Warren Morrison and J. W. Horton at Bell Telephone Laboratories.

eProject: Aura Watches

The world's first prototype analog quartz wristwatches were revealed in 1967: the Beta 1 revealed by the Centre Electronique Horloger (CEH) in Neuchâtel Switzerland, and the prototype of the Astron revealed by Seiko in Japan (Seiko had been working on quartz clocks since 1958).

In December 1969, Seiko produced the world's first commercial quartz wristwatch, the Seiko-Quartz Astron 35SQ which is now honored with IEEE Milestone [28]. The Astron had a quartz oscillator with a frequency of 8192 Hz and was accurate to 0.2 seconds per day, 5 seconds per month, or 1 minute per year. The Astron was released less than a year prior to the introduction of the Swiss Beta 21, which was developed by 16 Swiss Watch manufacturers and used by Rolex, Patek and Omega in their electroquartz models. The inherent accuracy and low cost of production has resulted in the proliferation of quartz clocks and watches since that time. By the 1980s, quartz technology had taken over applications such as kitchen timers, alarm clocks, bank vault time locks, and time fuses on munitions, from earlier mechanical balance wheel movements, an upheaval known in watchmaking as the quartz crisis.

Quartz timepieces have dominated the wristwatch and clock market since the 1980s. Because of the high Q factor and low temperature coefficient of the quartz crystal, they are more accurate than the best mechanical timepieces, and the elimination of all moving parts makes them more rugged and eliminates the need for periodic maintenance.

Commercial analog and digital wall clocks became available in 2014 that utilize a double oven quartz oscillator, accurate to 0.2 ppb. These clocks are factory-synchronized with the atomic time standard and typically do not require any further time adjustments for the life of the clock.

The next 3 decades saw the development of quartz clocks as precision time standards in laboratory settings; the bulky delicate counting electronics, built with vacuum tubes, limited their use elsewhere. In 1932 a quartz clock was able to measure tiny variations in the rotation rate of the Earth over periods as short as a few weeks. In Japan in 1932, Issac Koga developed a crystal cut that gave an oscillation frequency with greatly reduced temperature dependence. The National Bureau of Standards (now NIST) based the time standard of the US on quartz clocks between the 1930s and the 1960s, after which it transitioned to atomic clocks. The wider use of quartz clock technology had to await the development of cheap semiconductor digital logic in the 1960s. The revised 14th edition of Encyclopaedia Britannica stated that quartz clocks would probably never be affordable enough to be used domestically.

Eco-Drive Clock

Introducing the Eco-Drive Clock

Eco-Drive watches are watches that operate on the energy derived from the light of any light source. The watch uses extremely sensitive panels on the dial that absorb light energy converted into electricity and a charging device. The battery is completely mercury-free, which is an environmentally friendly solution.

History Of Eco-Drive Watch Technology

By about 1970, battery-powered quartz watches dominated the Japanese watch market and became the most popular watch line today. And at the same time the energy crisis began, it was this same reason that Citizen started looking for an alternative energy source for watches.

In 1976, Citizen launched the Cryston Solar Cell watch, the first product to use light energy to operate, with a photovoltaic cell placed on the dial to store light energy into the battery.

In 1980, Citizen watch engineers successfully developed a light-powered watch that could store up to 200 hours of power. When the battery is fully charged, photovoltaic cells can store light to generate electricity.

In 1995, the watch called Eco-Drive was officially born, marking a golden milestone in the history of Citizen brand. Since then, the name and logo Eco-Drive are recognized worldwide.

The Best Things Of An Eco-Drive Watch

- Break through with the use of light energy, helping users not to worry about running out of battery, running out of energy wherever you are (possibly in outer space).
- When the Eco-Drive is fully charged (the watch can be charged with any light source), the watch can work for 6 months or even 5 years (some models) if not exposed to sunlight, shining.
- The Eco-Drive movement is light and thin, with a thickness of just 4.2mm. This is the foundation for elegant and sophisticated design.
- Eco-Drive Citizen watches have never been blurred between thousands of models today and can hardly be outdated.
